

Project Abstract

This project presents the design and development of an OSINT-based Monitoring and Change Detection System aimed at automatically collecting data from multiple open-source intelligence platforms and identifying meaningful changes over time. The system continuously gathers publicly available information related to cybersecurity and threat intelligence, processes it through correlation and verification techniques, and detects significant variations while minimizing false positives.

By integrating multiple OSINT tools and data sources within a modular framework, the system correlates overlapping information to improve reliability and confidence in detected changes. A change detection mechanism analyzes historical and current data to recognize relevant modifications such as newly discovered assets, removed resources, or altered intelligence indicators. Verified and high-confidence changes are then presented to users as timely alerts.

The proposed solution enhances cybersecurity monitoring by providing accurate, automated, and scalable intelligence tracking. It contributes to research in open-source intelligence analysis and change detection methodologies, supporting security professionals in proactive threat identification and informed decision-making.
